

## Logical model of Drosophila EGF signaling pathway

Mbodj, Junion, Brun, Furlong and Thieffry (2013). Logical modelling of drosophila signalling pathways. Submitted to *Molecular BioSystems*.

Regulatory graph for Drosophila EGF pathway, displayed from ligand and receptor at the top to the main downstream effectors and a generic target node at the bottom. Rectangular and ellipsoid nodes denote ternary and Boolean components, respectively. Red blunt and green normal arrows denote activatory and inhibitory interactions, respectively.

## Overview

Four activating ligands, Spitz, Keren, Gurken and Vein have been identified for drosophila EGF receptors, called DER. Spitz (SPI) is the major ligand and is involved in most situations where the pathway is activated. Keren plays a minor, redundant role, while Gurken is used exclusively during oogenesis.

These ligands are produced as inactive transmembrane precursors, which are retained in the endoplasmic reticulum and needed to be processed by the chaperone protein Star. Processed ligands are directed into another compartment where they encounter Rhomboid (RHO) serine proteases, which cleave the ligand precursors within the transmembrane domain to release the active, secreted ligand form. RHO also cleaves and inactivates Star, attenuating the level of cleaved ligand that is produced. The fourth ligand, Vein, is produced as a secreted molecule, which is a weaker activating ligand used either to enhance signalling by other ligands or in specific situations such as muscle patterning. Binding of ligands to DER leads to dimerization and triggering of the canonical DRK/SOS/RAS/RAF/DSOR1/Rolled pathway. DRK (SH2-domain-containing protein) recruits

SOS (Son of sevenless, a guanine nucleotide exchange factor) to catalyze the exchange of RAS bound GDP for GTP exchange, thereby activating RAS. RAS then promotes the activation of RAF, leading to DSOR1 activation, and eventually to Rolled (RL) activation. RL inactivates transcriptional co-repressors, such as Aop, and activates transcription factors, such as Pointed (PNT) (O'Neill et al., 1994; Brunner et al., 1994). The transcriptional activator PNT is the major effector of the pathway. The protein Anterior open (AOP) is a constitutive repressor, which competes for PNT binding sites and can be removed from the nucleus and degraded upon phosphorylation by MAP kinases.

AOS (Argos), STY (Sprouty) and KEK (Kekkon) are inducible repressive elements involved in negative feedbacks. AOS is a secreted molecule, which sequesters the ligand SPI (Spitz). STY acts downstream of DER, but upstream of RAS and RAF, by recruiting GAP1 and blocking the ability of DRK to bind to its positive effector. KEK is a transmembrane protein forming a non-functional heterodimer with the receptor.

Constitutively expressed, CBL (E3 ligase) modulates DER signalling by recognizing activated, internalized receptor molecules and inducing their ubiquitination and degradation. CBL may also enhance the endocytosis of DER, following ligand binding. Modulation of DER signalling by CBL has been reported only in the follicle cells, which receive the Gurken signal from the oocyte (Levkowitz et al., 1999; Yokouchi et al., 1999; Waterman et al., 2000; Pai et al., 2000).

Our logical model represents a cell receiving different combinations of ligands binding (SPI or Vein or both) and express/receive different levels of inhibitory inputs (Aos, Sty, Cbl, Kek). The signalling pathway is characterized by no signalling, medium or high signalling process designed by multi-valued nodes.

We consider five main wild-type cellular situations:

- i. Cells secreting ligands but lacking Der activation (inhibition of Der), leading to no signalling.
- ii. Cells receiving medium signal with SPI expressed at level 1 and/or Vein expressed also at level 1, leading to medium signalling.
- iii. Cells receiving SPI at level of expression 1 (and/or Vein expressed at level 1) and in presence of an inhibitor (e.g. STY, AOS, or KEK), leading to no signalling.
- iv. Cells receiving SPI at level of expression 2 in the absence of inhibitors, leading to high signalling.
- v. Cells receiving SPI at level of expression 2 (and/or Vein expressed at level 1) in presence of an inhibitor (e.g. STY, AOS, or KEK,...), leading only to medium signalling.

## Description of regulatory graph components

Components	Values	Logical rules	Annotations
Aos		input	<ul style="list-style-type: none"> <li>● <a href="#">PMID:1606617</a></li> <li>● <a href="#">PMID:7651519</a></li> <li>● <a href="#">PMID:1576953</a></li> <li>● <a href="#">PMID:8565833</a></li> <li>● <a href="#">PMID:9367443</a></li> <li>● <a href="#">PMID:12648473</a></li> <li>● <a href="#">PMID:16123311</a></li> <li>● <a href="#">PMID:18369317</a></li> <li>● <a href="#">PMID:8026629</a></li> <li>● <a href="#">PMID:8812109</a></li> <li>● <a href="http://flybase.org/reports/FBgn0004569.html">http://flybase.org/reports/FBgn0004569.html</a></li> </ul> <p>AOS (Argos ) is a secreted protein containing an EGF-like domain (Freeman et al., 1992), which inhibits DER stimulation by activating ligands such as SPI (Schweitzer et al 1995; Wasserman and Freeman, 1998). AOS is induced in response to DER signalling in the cells receiving high levels of DER activation, and plays a major role in restricting the activation range of the activating ligands (Golembo et al., 1996; Queenan et al., 1997). AOS is secreted and reaches several cell rows away from the site of production. It maintains a steady-state level of signalling such that the cells receiving maximal levels of SPI maintain DER activation, in spite of the production of AOS, while in the cells further away from the source, AOS attenuates activation by SPI (Shiloh et al., 2003, 2005; Yogev et al., 2008). AOS and Kekkone (another inhibitor), are expressed in exactly the same pattern (Sawamoto et al., 1994; Musacchio and Perrimon, 1996).</p>
Cbl		input	<ul style="list-style-type: none"> <li>● <a href="#">PMID:11051547</a></li> <li>● <a href="#">PMID:15282549</a></li> <li>● <a href="http://flybase.org/reports/FBgn0020224.html">http://flybase.org/reports/FBgn0020224.html</a></li> </ul> <p>CBL is an E3 ligase that recognizes the activated, endocytosed DER and induces its ubiquitination and degradation. CBL may also enhance the endocytosis of DER, following ligand binding. Although CBL is broadly expressed, it only modulates DER signalling in the follicle cells, which receive the Gurken (another ligand) signal from the oocyte. In <i>cbl</i> mutant cells, DER is hyper-activated, leading to the repression of genes such as <i>pipe</i> (Pai et al., 2000; Gur et al., 2004).</p>
Cnk		input	<ul style="list-style-type: none"> <li>● <a href="#">PMID:9814705</a></li> <li>● <a href="#">PMID:10860999</a></li> <li>● <a href="#">PMID:16326394</a></li> <li>● <a href="#">PMID:14517245</a></li> <li>● <a href="#">PMID:15660123</a></li> <li>● <a href="#">PMID:16600911</a></li> </ul> <p>CNK (Connector Enhancer of KSR) is required upstream of RAF (Therrien et al., 1998) for the control various processes, including cell proliferation/survival, differentiation and migration (Therrien et al., 1998; Baonza et al., 2000; Cabernard and Affolter, 2005).</p>

			<p>CNK directly associates with the kinase domain of RAF via a short amino-acid sequence, called the RAF-interacting motif (RIM), and modulates RAF activity according to the EGF signalling status (Douziech et al., 2003; Laberge et al., 2005).</p> <p>When there is no signalling, the binding of CNK to RAF is inhibited by a second motif adjacent to the RIM, called the inhibitory sequence (IS). When the pathway is activated, CNK integrates SRC42 and RAS activities, leading to RAF activation (Laberge et al., 2005).</p>
